

# **Git — What, Why and How To Use It**

Imagine you're cooking a delicious meal. Everything is almost ready, only the last bits are left on the stove when suddenly you get a call. It's your best friend whom you haven't spoken to in ages. Great, now you have good food and good company. Distracted by the phone and your bestie's general life drama, you realize that your precious meal is now burnt garbage. With your heart in shambles you wish that there was some to undo the done, to go back in time and save your food. Well your food might be beyond saving, but with Git at least your code can be reverted to the previous version.

## **What is Git ?**

Git, in most basic terms, is a system that tracks changes across files and folders so that specific versions can be recalled later (like recalling the pre burnt version of food so you can cook it again properly). This system, also known as version control system, is used to view changes in the files over a period, compare versions, check who modified what among many other things.

## **Why Git ?**

Git is a powerful tool that allows for open source and collaborative developments. Through branching, a process that allows developers to divert from the main project to add a bug or feature, multiple developers can work on different features at the same time without affecting the main project. Branches in git are easy and cheap to merge, unlike in centralized version control systems. This is what makes it an extremely popular choice for developers working on any kind of project.

## **Basic Terms—**

Repository: defined as “a folder that can track changes”, it is a directory that stores files, source codes and basically a collection of things whose history can be maintained and can be tracked.

Untracked: a place to modify, edit and create files

Commit: saves the changes of the file into the working repository

### Tracked:

1. Staged: files that are ready to be committed to the repository.
2. Modified: when changes are made to a file, git sees them as modified and displays it.

## Git Commands—

Git init: to initialize a repository, git creates a hidden .git directory. This hidden repository is what separates regular directory from Git repository

```
● (base) tanya@Tanyas-MacBook-Air task 2 gdsc % git init
hint: Using 'master' as the name for the initial branch. This default branch name
hint: is subject to change. To configure the initial branch name to use in all
hint: of your new repositories, which will suppress this warning, call:
hint:
hint:   git config --global init.defaultBranch <name>
hint:
hint: Names commonly chosen instead of 'master' are 'main', 'trunk' and
hint: 'development'. The just-created branch can be renamed via this command:
hint:
hint:   git branch -m <name>
Initialized empty Git repository in /Users/tanya/Desktop/task 2 gdsc/.git/
○ (base) tanya@Tanyas-MacBook-Air task 2 gdsc %
```

Git add: used to save changes to the file and push the file to the staging area

```
● (base) tanya@Tanyas-MacBook-Air gdsc % git init
Reinitialized existing Git repository in /Users/tanya/Desktop/gdsc/.git/
● (base) tanya@Tanyas-MacBook-Air gdsc % git add task1.txt
○ (base) tanya@Tanyas-MacBook-Air gdsc %
```

Git commit: creates a commit, basically a snapshot of the repository in its current state

```
● (base) tanya@Tanyas-MacBook-Air task 2 gdsc % git commit -m 'first commit'
[master (root-commit) 6e66748] first commit
Committer: Tanya <tanya@Tanyas-MacBook-Air.local>
Your name and email address were configured automatically based
on your username and hostname. Please check that they are accurate.
You can suppress this message by setting them explicitly. Run the
following command and follow the instructions in your editor to edit
your configuration file:

    git config --global --edit

After doing this, you may fix the identity used for this commit with:

    git commit --amend --reset-author

1 file changed, 0 insertions(+), 0 deletions(-)
create mode 100644 task2.txt
○ (base) tanya@Tanyas-MacBook-Air task 2 gdsc %
```

Git branch: used to create a new branch/check the names of existing branches

```
● (base) tanya@Tanyas-MacBook-Air task 2 gdsc % git branch  
  admin  
  * master  
○ (base) tanya@Tanyas-MacBook-Air task 2 gdsc %
```

Git checkout: used to switch branches

```
● (base) tanya@Tanyas-MacBook-Air task 2 gdsc % git checkout admin  
Switched to branch 'admin'  
○ (base) tanya@Tanyas-MacBook-Air task 2 gdsc %
```

Git push: used to upload all local files and commits to corresponding local branch.

```
⊗ (base) tanya@Tanyas-MacBook-Air task 2 gdsc % git remote add origin https://github.com/spaceluvr/task-2-gdsc.  
git  
error: remote origin already exists.  
● (base) tanya@Tanyas-MacBook-Air task 2 gdsc % git push -u origin master

## Conclusion—

While Git might be intimidating to use at first, it is incredibly useful and makes development easier, flexible and faster. Once learnt, you will never want to use anything that's not Git.
